

Tree Data Structures

261217 Data Structures for Computer Engineers

Patiwet Wuttisarnwattana, Ph.D.

patiwet@eng.cmu.ac.th

Computer Engineering, Chiang Mai University

Why do we need Tree?

- Lists, Stacks, and Queues are linear relationships
 - Accessing time can be super fast $O(1)$
 - But searching for a key takes $O(n)$
 - Some say this is too slow
 - Can you find something that the search is faster than $O(n)$
- Well, Tree can be the answer

What is Tree?

▣ What is Tree

- ▣ Tree consists of nodes that contain data
- ▣ Tree can contain no node (empty)
- ▣ **A node can point to one or more nodes**
- ▣ A node can point to null (leaf node)
- ▣ A node that no other node point to it; is called **root** node
- ▣ **Tree contains no loop/cycle of nodes**

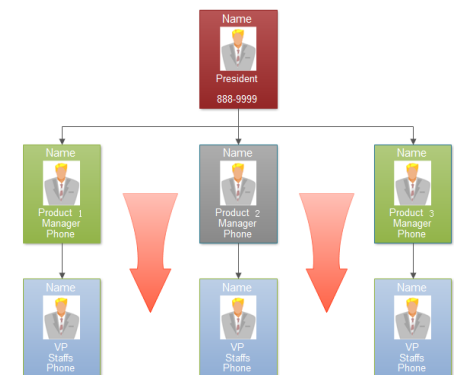

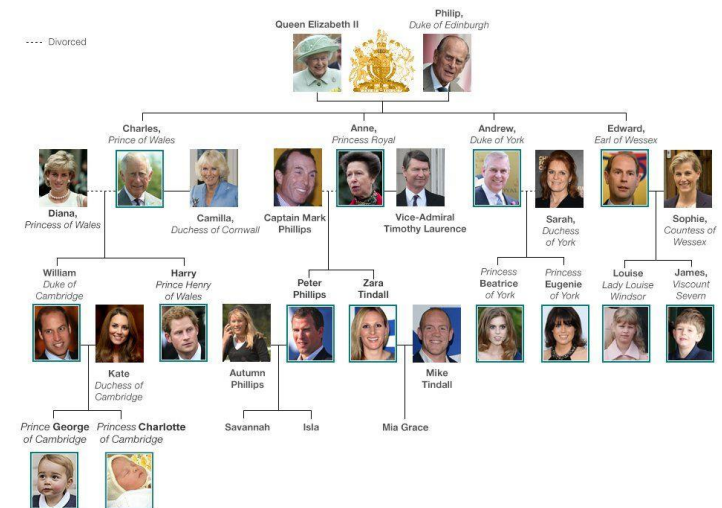

Trees

Information often contains hierarchical relationships

- Family
- File directories or folders
- Moves in game
- Hierarchies in organizations

Part of the filesystem tree

Tree Terminology

A tree data structure stores information in *nodes*

- Similar to linked lists:
 - There is a first node, or *root*
 - Each node has variable number of references to successors
 - Each node, other than the root, has exactly one node pointing to it
 - In the diagram, the line that connected between nodes is called edge
 - The edge should be directed (either be unidirected or bidirected)

Parent and Child

All nodes will have zero or more child nodes or *children*

- I has three children: J, K and L

For all nodes other than the root node, there is one parent node

- H is the parent I

Node Degree

The *degree* of a node is defined as the number of its children:

$$\text{deg}(I) = 3$$

Nodes with the same parent are *siblings*

- J, K, and L are siblings

Phylogenetic tree

Phylogenetic trees have nodes with degree 2 or 0:

Wesley-Hunt, G. D.; Flynn, J. J. "Phylogeny of the Carnivora: basal relationships among the Carnivoramorpha, and assessment of the position of 'Miacoidea'"

Leaf Nodes and Internal Nodes

Nodes with degree zero are also called *leaf nodes*

All other nodes are said to be *internal nodes*, that is, they are internal to the tree

Leaf Nodes

Leaf nodes:

Wesley-Hunt, G. D.; Flynn, J. J. "Phylogeny of the Carnivora: basal relationships among the Carnivoramorpha, and assessment of the position of 'Miacoidea'"

Internal Nodes

Internal nodes:

Wesley-Hunt, G. D.; Flynn, J. J. "Phylogeny of the Carnivora: basal relationships among the Carnivoramorpha, and assessment of the position of 'Miacoidea'"

Unordered vs Ordered Trees

These trees are equal if the order of the children is ignored

- *unordered trees*

They are different if order is relevant (*ordered trees*)

- We will usually examine ordered trees (linear orders)
- In a hierarchical ordering, order is not relevant

Root node

- The shape of a rooted tree gives a natural flow from the *root node*, or just *root*
- Every node grows from the root
- Tree in Data Structure grows upside down

Path

A **path** is a sequence of nodes

$$(a_0, a_1, \dots, a_n)$$

where a_{k+1} is a child of a_k is

The **length** of this path is n

A tree with N nodes always has $N-1$ edges

E.g., the path (B, E, G)
has length 2

Loops in Tree?

- Two nodes in a tree have at most one path between them
- Can a non-zero path from node N reach node N again?

No. Trees can never have cycles (loops)

Path Example

Paths of length 10 (11 nodes) and 4 (5 nodes)

Wesley-Hunt, G. D.; Flynn, J. J. "Phylogeny of the Carnivora: basal relationships among the Carnivoramorpha, and assessment of the position of 'Miacoidea'"

Distance Measurement

- **Length** of a path = number of edges
- **Depth** of a node N = length of path from root to N
- **Height** of node N = length of longest path from N to a leaf
- **Depth of tree** = depth of deepest node
- **Height of tree** = height of root

Node Depth

For each node in a tree, there exists a unique ***path from the root node to that node***

- What is depth of the node E?
☐ 2
- What is depth of the node L?
☐ 3

Node Depth and Tree Depth

Wesley-Hunt, G. D.; Flynn, J. J. "Phylogeny of the Carnivora: basal relationships among the Carnivoramorphans, and assessment of the position of 'Miacoidea'"

Height of Node and Tree

- The height of a node is the path length from the node to the deepest descendant.
- The height of a tree is the path length from root node to the deepest leaf.
- The height of a tree with a single node is 0
- The height of a leaf node is 0
- The height of a tree is equal to the depth of the tree
- For convenience, we define the height of the empty tree to be -1

Node Height vs Tree Height

Wesley-Hunt, G. D.; Flynn, J. J. "Phylogeny of the Carnivora: basal relationships among the Carnivoramorpha, and assessment of the position of 'Miacoidea'"

Ancestor and Descendent

If a path exists from node a to node b :

- a is an *ancestor* of b
- b is a *descendent* of a

Thus, a node is both an ancestor and a descendant of itself

- We can add the adjective *strict* to exclude equality: a is a *strict descendant* of b if a is a descendant of b but $a \neq b$

The root node is an ancestor of all nodes

Ancestor and Descendent

The descendants of node B are B, C, D, E, F, and G:

The ancestors of node I are I, H, and A:

Descendants

All descendants (including itself) of the indicated node

Wesley-Hunt, G. D.; Flynn, J. J. "Phylogeny of the Carnivora: basal relationships among the Carnivoramorpha, and assessment of the position of 'Miacoidea'"

Ancestors

All ancestors (including itself) of the indicated node

Wesley-Hunt, G. D.; Flynn, J. J. "Phylogeny of the Carnivora: basal relationships among the Carnivoramorpha, and assessment of the position of 'Miacoidea'"

Alternative Definition of Tree

Another approach to a tree is to define the tree recursively:

- A tree can be represented by a root node
- Any node can be a root node
- A child node of a node is also a root node of a tree (sub-tree)

Example: XHTML

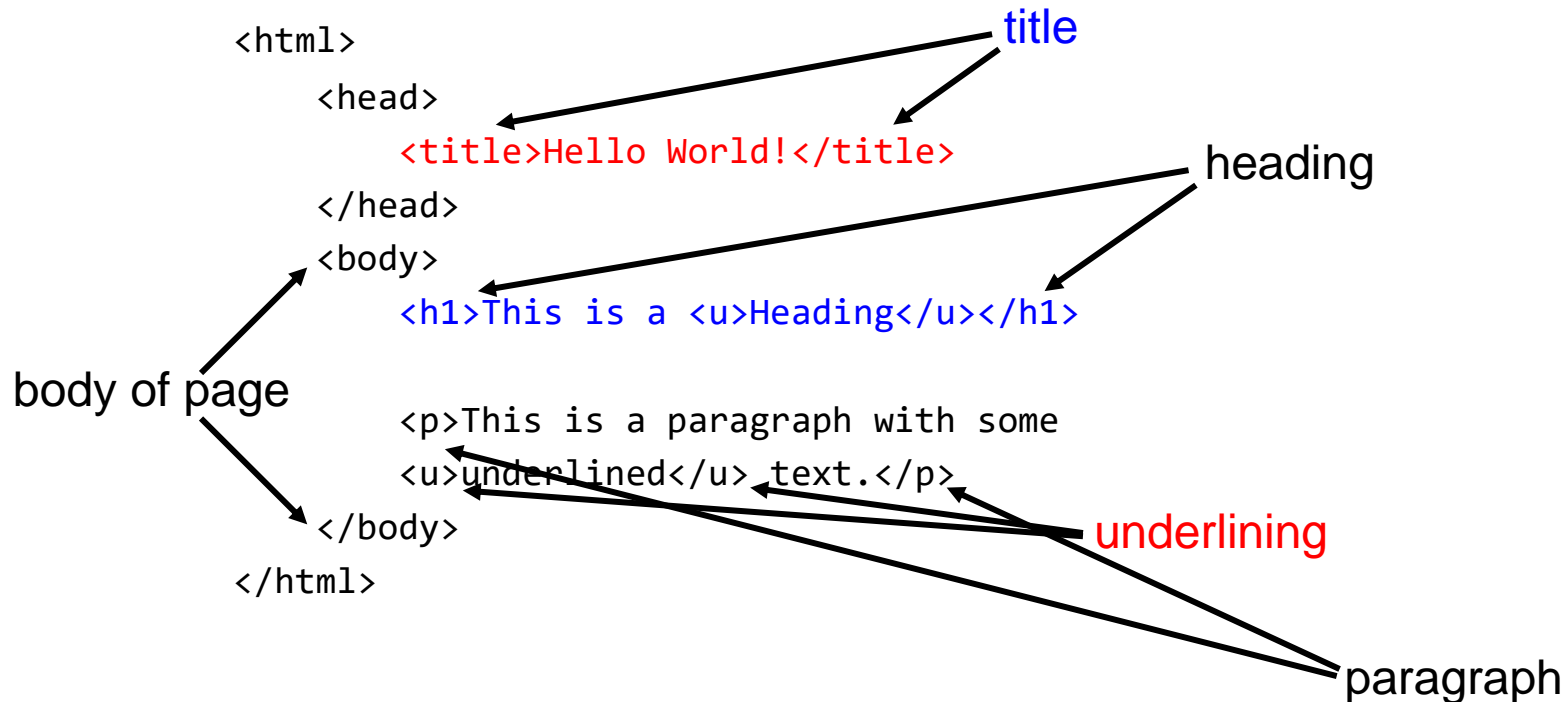

- The XML of XHTML has a tree structure
- Consider the following XHTML document

```
<html>
  <head>
    <title>Hello World!</title>
  </head>
  <body>
    <h1>This is a <u>Heading</u></h1>

    <p>This is a paragraph with some
      <u>underlined</u> text.</p>
  </body>
</html>
```

Example: XHTML

- The XML of XHTML has a tree structure
- Consider the following XHTML document

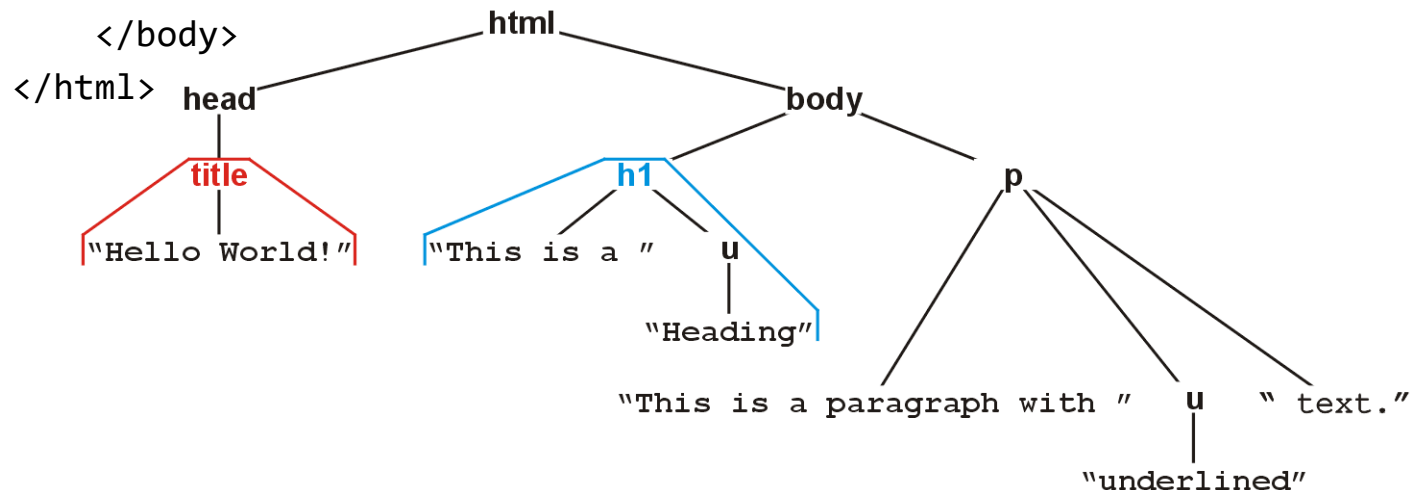

Converting XML to Tree Data Structure

The nested tags define a tree rooted at the HTML tag

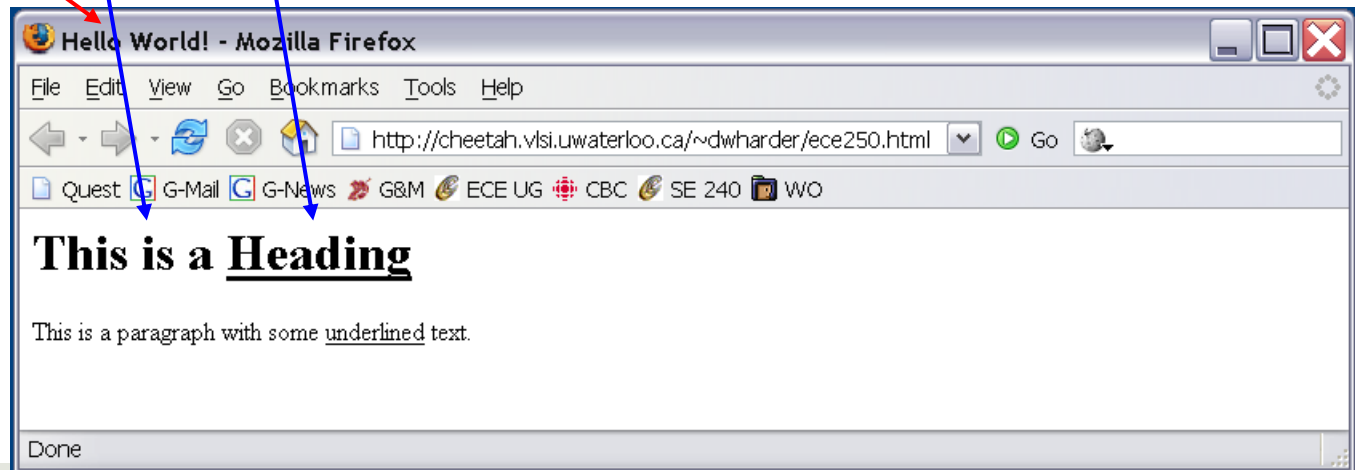

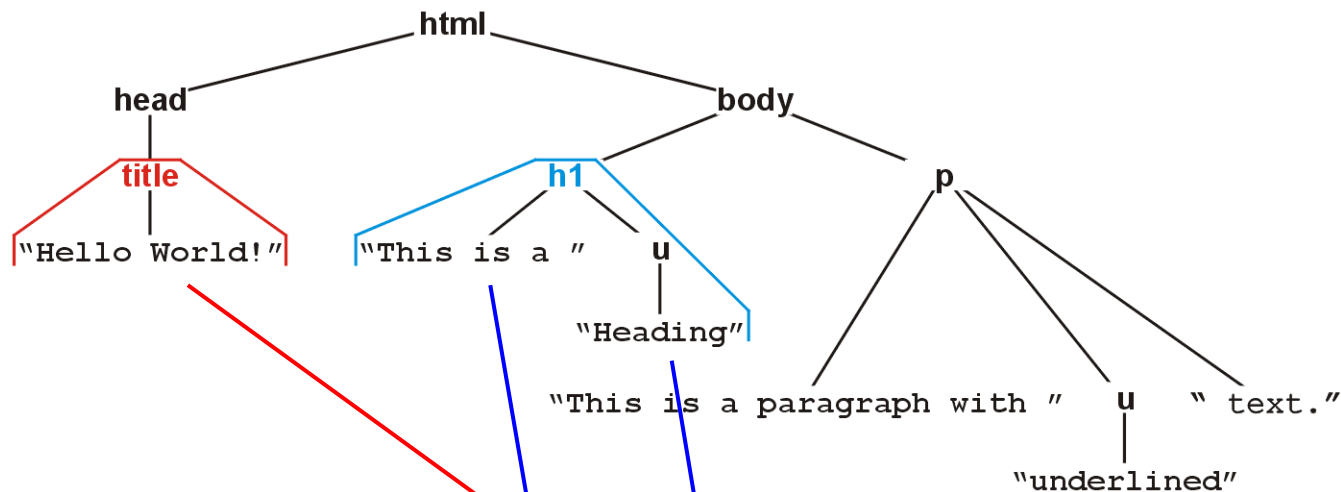

```
<html>
  <head>
    <title>Hello World!</title>
  </head>
  <body>
    <h1>This is a <u>Heading</u></h1>
```

```
    <p>This is a paragraph with some
    <u>underlined</u> text.</p>
```

Example: XHTML

Web browsers render this tree as a web page

Implementation of Trees (K-ary Tree)

Pointer-based Implementation

class Node

// Required:

Object Key;

// K-ary Tree

Node child1, child2, ..., childK

// Optional:

// For bidirectional tree

Node parent;

Tree data structure

```
class Tree{  
  Node root  
}
```

Implementation of Binary Trees

Pointer-based Implementation

class Node

Object Key;
Node left;
Node right;

Node parent; // optional

```
class Tree{  
  Node root  
}
```

Binary Tree Structure (applicable to K-nary tree)

class Node

Key

LeftChild

RightChild

Potential issue?

class Node

// Required:

Object Key;

// K-ary Tree

Node child1, child2, ..., childK

// Optional:

// For bidirectional tree

Node parent;

- The implementation is not flexible (It is not a generic tree)
- What should be k? Magic!
- If the tree has different number of possible children ($> k$), the class will need to be re-implemented (useless code; add more variables)

Version 2: Use List of Nodes instead of a fixed number of pointers to Nodes

List-based Implementation

class Node

// Required:

Object Key;

// NodeList can be DynamicArray or LinkedList

NodeList listOfChildren;

// Optional:

Node parent;

```
class Tree{  
  Node root  
}
```

List-based Implementation

- Now that each node can have a flexible number of children
- Slightly confusing for implementing
 - Need loop for accessing the children
 - Tree traversal/search implementation might be complicated

Potential issues with Version 2?

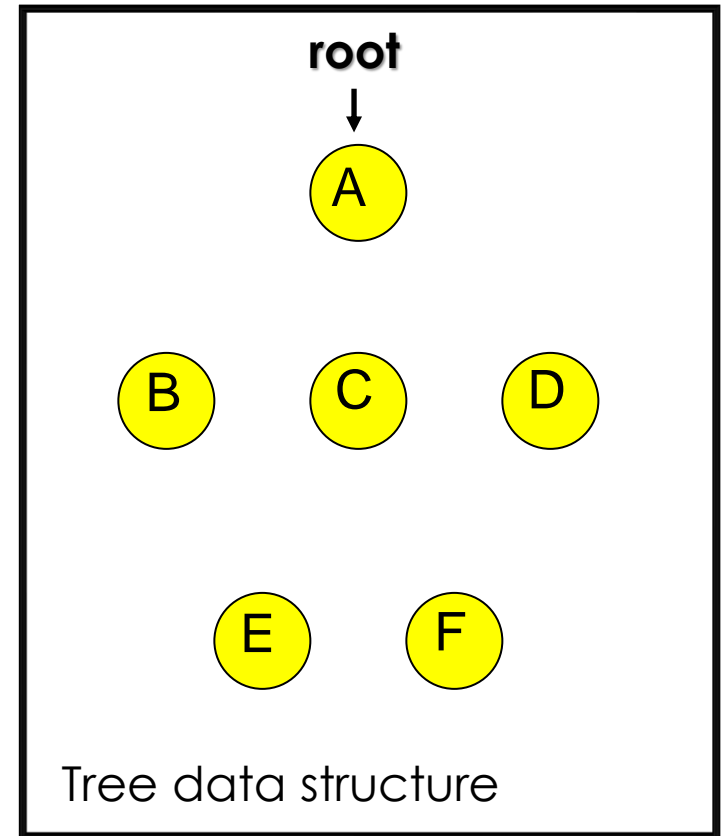

- It's quite complicated
 - Accessing the children requires implementation of loop
 - Tree traversal implementation could be complicated
- In general sense, siblings should know each other
 - Version 2: A node knows only its children; or its parent (if you implement the parent pointer)
 - It does not directly know its siblings; need to go up one step to the parent and then go down to the sibling nodes.
 - Solution is to implement sibling pointer but node cycle may form and tree data structure will be violated
 - Version 3 is introduced

Instead of multiple pointers/list, let's fix to two pointer variables

How to re-define a node so that it can point to at most two nodes

```
class Tree{  
  Node root  
}
```

```
class Tree{  
  Node root  
}
```

Instead of multiple pointers/list, let's fix to two pointer variables

How to re-define a node so that it can point to at most two nodes

```
class Tree{  
  Node root  
}
```

```
class Tree{  
  Node root  
}
```

Version 3: Generic Tree Implementation

Pointer-based Implementation

class Node

// Required:

Object Key;

// K-ary Tree

Node firstChild;

Node nextSibling;

// Optional:

// For bidirectional tree

Node parent;

```
class Tree{  
  Node root  
}
```

Generic Tree Implementation

root

Nodes
of same
depth

class Node

Key

firstChild

nextSibling

Binary Tree

- Every node has at most two children
- Most popular tree in computer engineering field
- If I do not say otherwise, we will assume that we are talking about Binary Trees for the rest of the course.
- Given a binary tree with depth **d**, what is the possible number of nodes (**N**)?
- Given a number of nodes **N**, what is the minimum depth of a binary tree?

Minimum depth vs Node count

- At depth d , you can have $N = 2^d$ to $2^{d+1}-1$ nodes
- minimum depth d is $\Theta(\log N)$

$T(n) = \Theta(f(n))$ means

$T(n) = O(f(n))$ and $f(n) = O(T(n))$,

i.e. $T(n)$ and $f(n)$ have the **same** growth rate

$d=2$

$N=2^2$ to 2^3-1 (i.e, 4 to 7 nodes)

Minimum depth vs Node count

- What is the maximum depth of a binary tree?
 - Degenerate case: Tree is a linked list!
 - Maximum depth = $N - 1$

Thought Questions

- If a target key is often stored at the leaf nodes
 - What is the complexity of the searching for a key in a tree with the maximum depth (degenerate tree)?
 - What is the complexity of the searching for a key in a tree with the minimum depth (complete tree)?

Height Measurement

Height = ?

Height = ?

Height = ?

Height Measurement Algorithm

```
int Height( Node node )
```

```
if node == null
```

```
    return -1
```

```
else
```

```
    return 1 + max( Height(node.left), Height(node.right) )
```

Tree Size Measurement

Tree Size (N) = ?

Tree Size (N) = ?

Tree Size (N) = ?

Tree Size Measurement Algorithm

Tree Size (N) = 5

Tree Size (N) = 7

Tree Size (N) = 6

```
int Size( Node node )
```

```
if node == null
```

```
    return 0
```

```
else
```

```
    return 1 + Size(node.left) + Size(node.right)
```

Tree Traversal (Walking a Tree)

- We want to visit all nodes of the tree
 - Searching for a key in an unordered tree ($O(n)$)
 - Re-evaluate values of one or more nodes
 - Print all the values contains within the tree ($\Theta(n)$)
- Traversal order: Breadth-first and Depth-first
 - **Breadth-first:** We traverse all nodes at one level before progressing to the next level
 - e.g. Users tend to place files are usually places at the earlier folders rather than deeper subfolder
 - **Depth-first:** We completely traverse one sub-tree to before exploring a sibling sub-tree
 - e.g. Important data often stored at the leaves of the tree (such as operands) which should be read first before the internal nodes (operators)

Breadth-first Traversal (Level Traversal)

Output:

Breadth-first Traversal (Level Traversal)

Output: Matthew, Mark, Luke, John, James, Peter, Jude, Paul, Timothy

Breadth-first Traversal implementation using Queue

LevelTraversal (Node node)

```
if node == null
    return
else
    Queue q
    q.Enqueue( node )
    while ( not q.Empty() )
        node = q.Dequeue()
        Print( node.key ) // Do something to the node
        if node.left ≠ null
            q.Enqueue( node.left )
        if node.right ≠ null
            q.Enqueue( node.right )
```

BFT using Q

Output:

Queue:

BFT using Q

Enqueue(Matthew)

```
while ( not q.Empty() )  
    node = q.Dequeue()  
    Print( node.key )  
    if node.left ≠ null  
        q.Enqueue( node.left )  
    if node.right ≠ null  
        q.Enqueue( node.right )
```

Output:

Queue: Matthew

BFT using Q

Dequeue ()

```
while ( not q.Empty() )  
    node = q.Dequeue()  
    Print( node.key )  
    if node.left ≠ null  
        q.Enqueue( node.left )  
    if node.right ≠ null  
        q.Enqueue( node.right )
```

Output: Matthew
node

Queue:

BFT using Q

Enqueue (node.left)

```
while ( not q.Empty() )  
    node = q.Dequeue()  
    Print( node.key )  
    if node.left != null  
        q.Enqueue( node.left )  
    if node.right != null  
        q.Enqueue( node.right )
```

Output: Matthew
node

Queue: Mark

BFT using Q

Enqueue (node.left)

```
while ( not q.Empty() )  
    node = q.Dequeue()  
    Print( node.key )  
    if node.left ≠ null  
        q.Enqueue( node.left )  
    if node.right ≠ null  
        q.Enqueue( node.right )
```

Output: Matthew
node

Queue: Mark, Luke

BFT using Q

Dequeue ()

```
while ( not q.Empty() )  
    node = q.Dequeue()  
    Print( node.key )  
    if node.left != null

Depth-first Traversal Implementation using Recursion

- We completely traverse one sub-tree before exploring a sibling sub-tree
- We can implement DFT using
 - Stack
 - Recursion
- Three modes of traversal
 - PreOrder, InOrder, PostOrder

PreOrder: 2, 1, 3

InOrder: 1, 2, 3

PostOrder: 1, 3, 2

Non-recursive Implementation of Depth-first Traversal

nonRecursiveDFT (Node node)

```
if node == null
    return
else
    Stack s
    s.push( node )
    while ( not s.Empty() )
        node = s.Pop()
        Print( node.key ) // Do something to the node
        if node.right ≠ null
            s.push( node.right )
        if node.left ≠ null
            s.push( node.left )
```

DFT using Stack

Output:

Unordered Tree Summary

- Tree is Data Structure with a node that can point to multiple nodes
- Searching a key in unordered tree takes $O(n)$
- Degenerate trees look like Linked list which takes $\Theta(n)$ to build
- If the target key tends to be in the earlier nodes, Breadth-first search is the best strategy
- If the target key tends to be in the deeper nodes or leaf nodes, Depth-first search is the best strategy
- Traversal can be: PreOrder, InOrder, or PostOrder
- Traversal implementation can be either recursive or non-recursive
- Non-recursive implementation of BFT is to use Q whileas DFT is to use Stack
